

Script-Controlled ACL – Restrict Record Access Based on Field Value

Phase 8: Project Demonstration

8.1 Demo Flow (approx. 8-10 minutes)

Step	Demo action	What to show
1	Introduce the problem	Student data of all branches in one table; need branch-level restriction
2	Show setup	EEE User, roles bb1-bb4, table u_institution_details with sample records
3	Show the read ACL	Advanced ACL, requires bb1, data condition Branch is EEE, script
4	Impersonate EEE User (bb1)	Only EEE records displayed
5	Impersonate user without role	"No records to display"
6	Impersonate Admin	All records displayed
7	Add bb2, bb3, bb4 progressively	New button, inline edit (Description), Delete with confirmation
8	Conclude	Summary of security outcomes and possible improvements

8.2 Key Talking Points

- ACLs are evaluated on role + data condition + script; all must pass.
- Admin bypass is intentional so administrators never lose visibility.
- Each operation has its own ACL and role, giving least-privilege control.

8.3 Conclusion

The project successfully restricts access to student records by the Branch field using a script-controlled ACL, and extends the model with separate CREATE, WRITE and DELETE ACLs. Verification through impersonation confirmed that bb1 users see only EEE records, users without the role see nothing, and administrators see everything.
